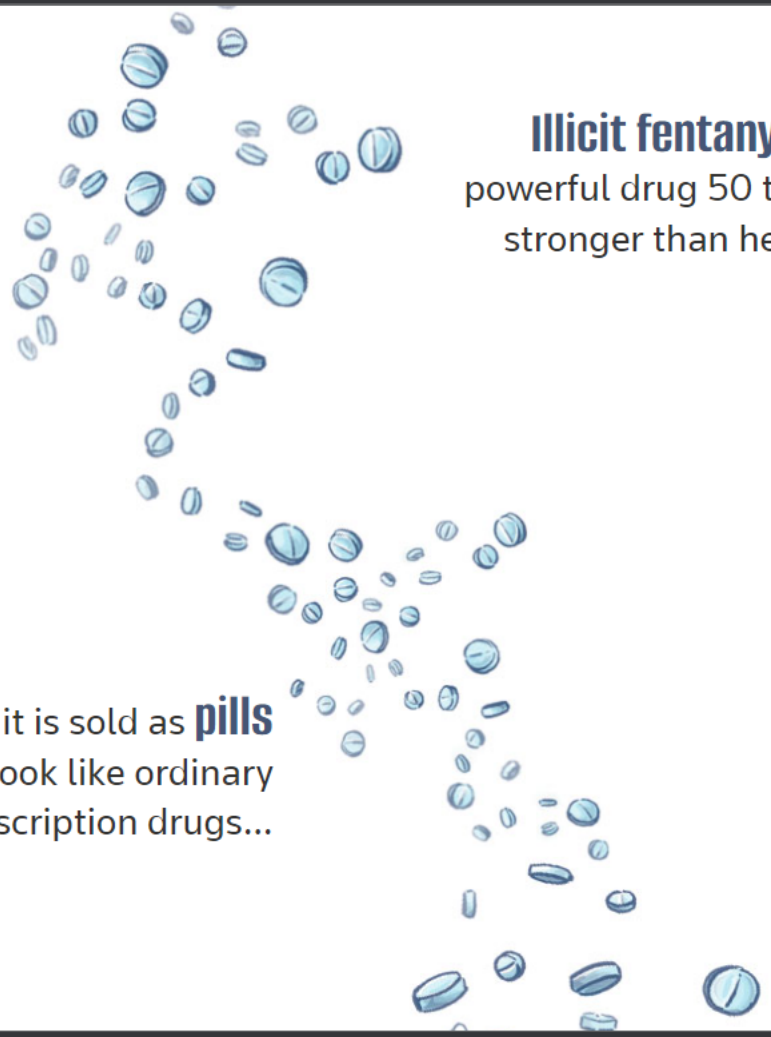
Fentanyl and adulterants

Tariffs and border militarization to stop the flow of fentanyl???

Dan Nauts, MD, FASAM

6/11/2025

The ease with which our reporters bought the drug-making chemicals exposed holes in the world's regulatory framework and law enforcement.

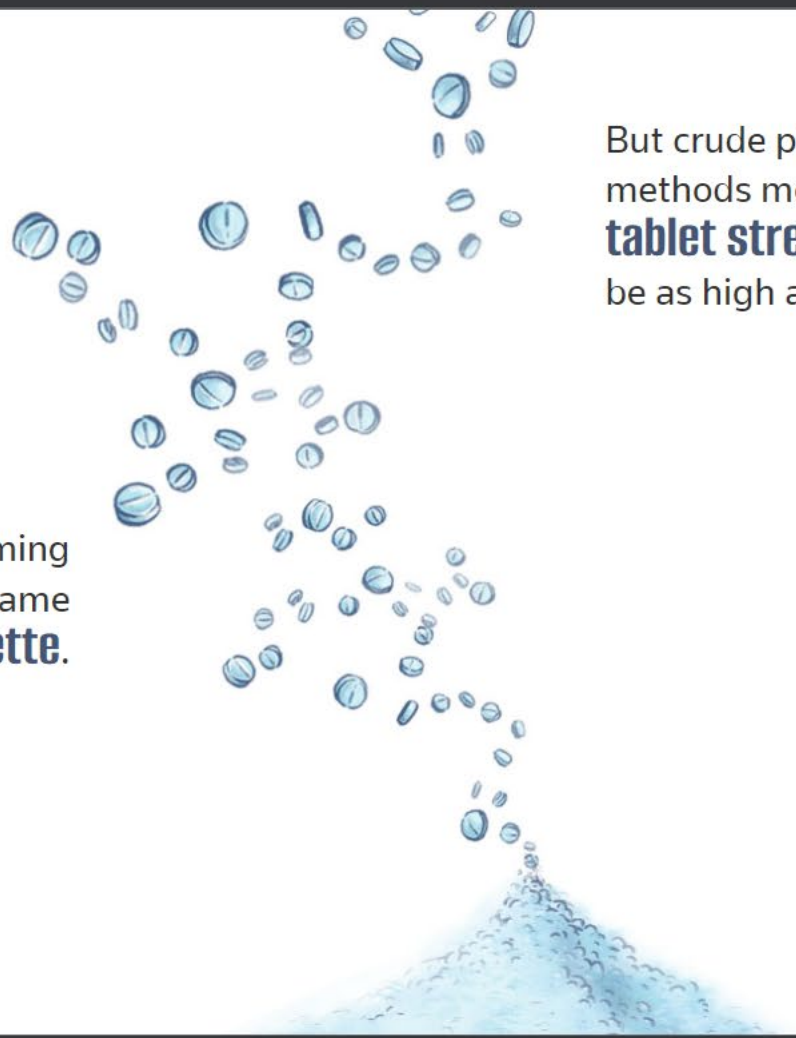


Illicit fentanyl is a powerful drug 50 times stronger than heroin.

Often, it is sold as **pills** that look like ordinary prescription drugs...

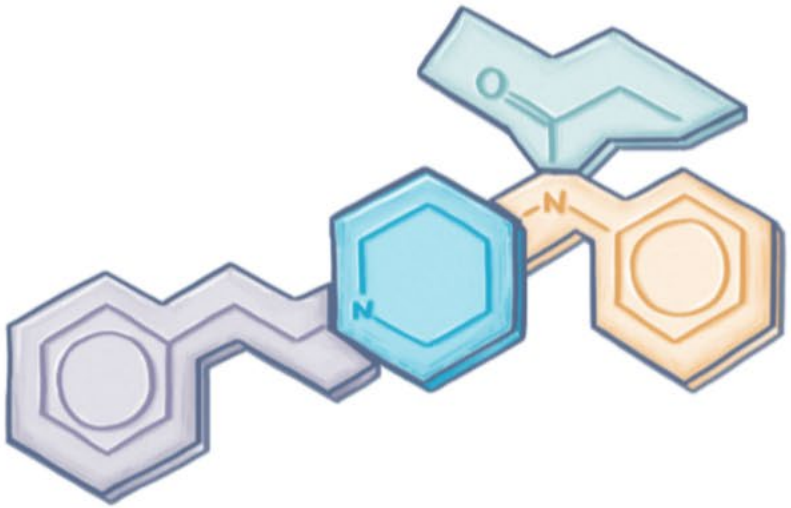
An average pill contains at least **2 mg** of fentanyl. That's a potentially lethal dose, the U.S. Drug Enforcement Administration (DEA) says.

...such as round **blue tablets** designed to look just like real oxycodone pills.



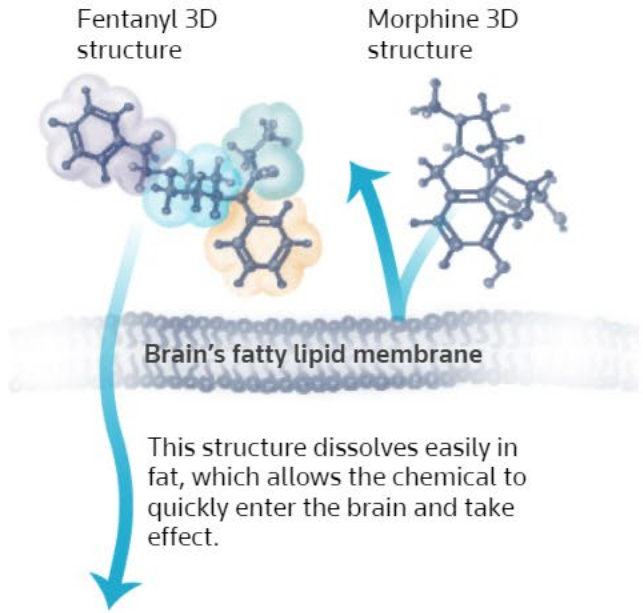
But crude pill-pressing methods means the **tablet strength** can be as high as 8.4 mg.

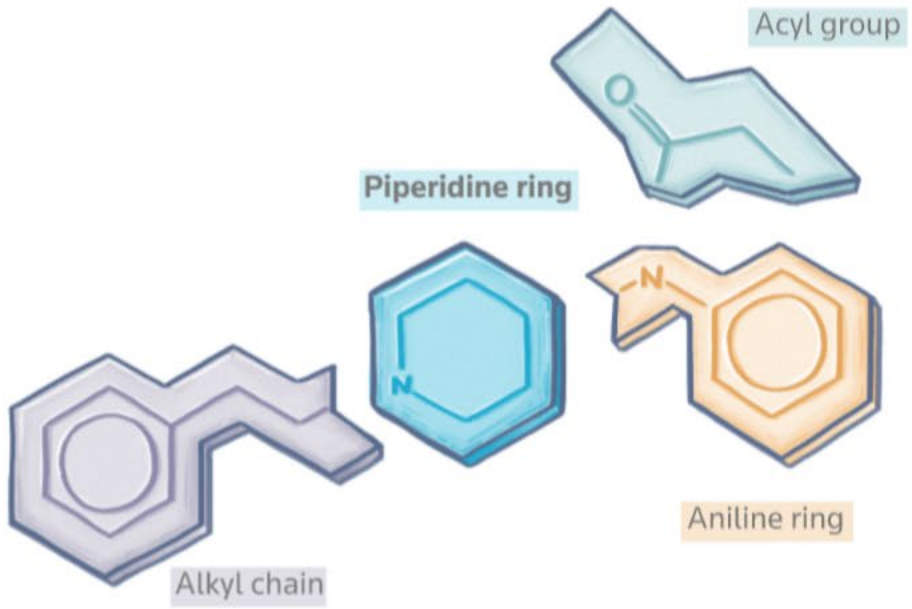
This turns consuming these pills into a game of **Russian roulette**.

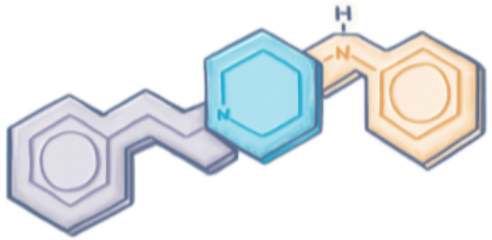


To understand these chemistry tricks, first consider the basic structure of fentanyl.

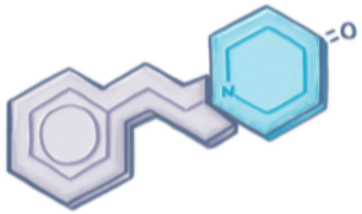
Fentanyl is much stronger than other opioids because its unique molecular structure allows it to easily enter parts of the brain that control pain and emotions.



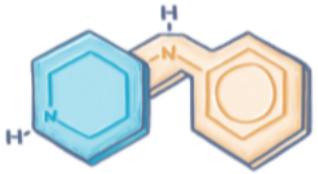




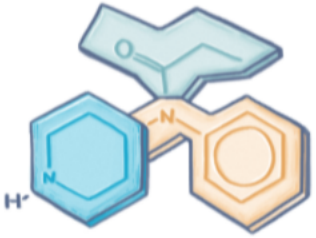
4-ANPP



NPP

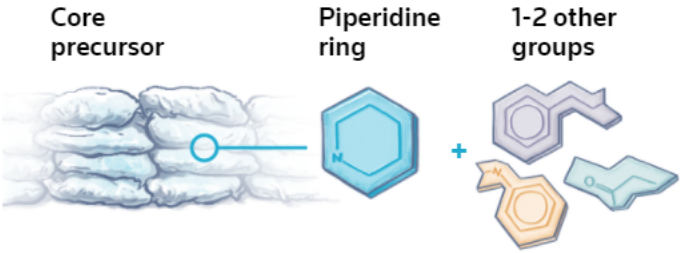


4-AP



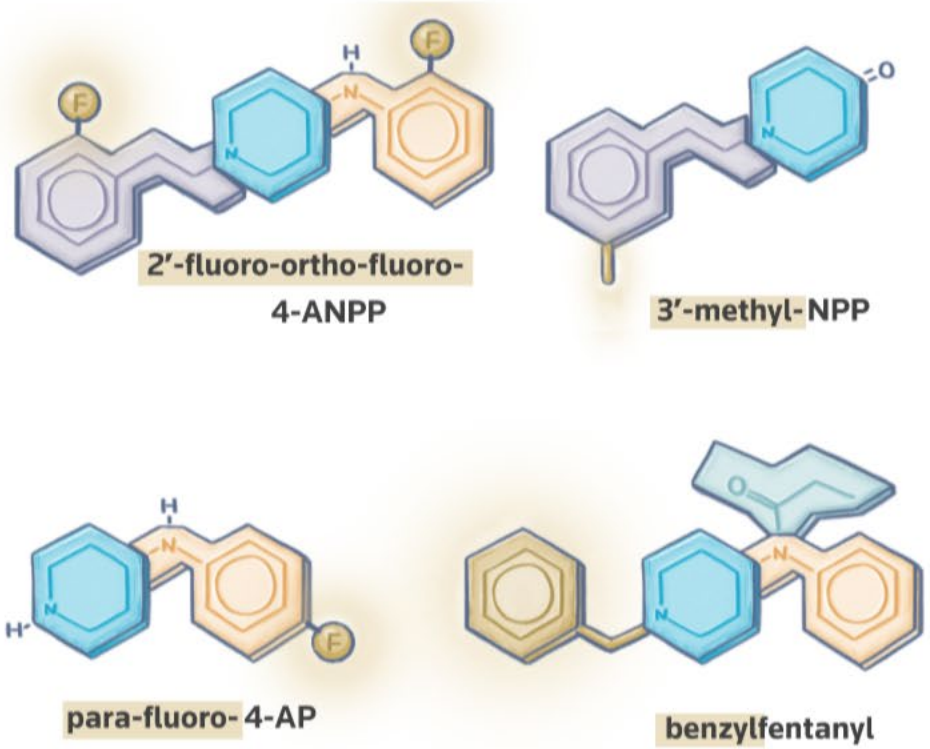
norfentanyl

Core precursors are chemical compounds made up of a piperidine ring and one or more of fentanyl's three other molecular groups. Here are four examples used by illicit makers.



But among these are the precursors that governments have placed the toughest restrictions on because they make producing street fentanyl such a snap. For example, the U.S. government tightly controls 4-ANPP and norfentanyl since they're what are known as immediate precursors, only one chemical reaction away from fentanyl itself.

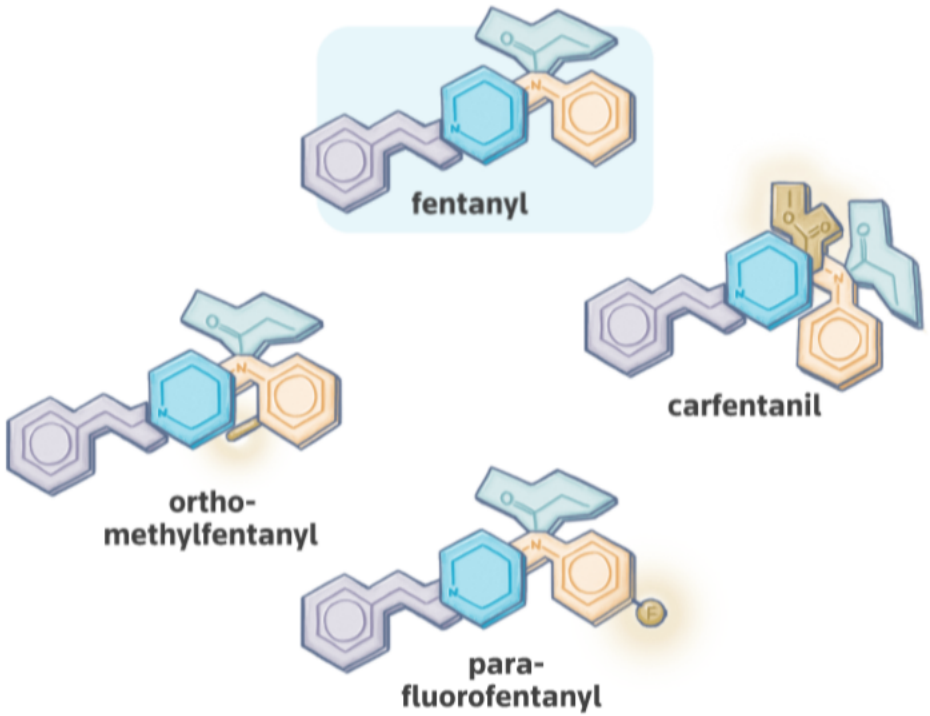
This is where creative chemistry comes in.



One way illicit fentanyl producers get around these regulations is to use **designer precursors** that have a similar, but slightly different chemical structure.

Imagine a Mr. Potato Head with its head, ears and nose – but in this case, the ears are gold, not the standard pink. The toy still looks and functions the same as the original.

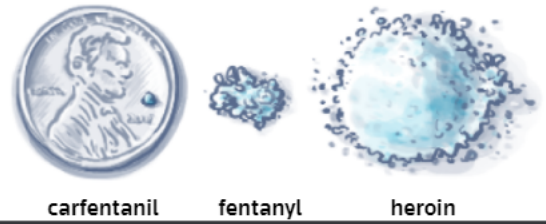
The chemistry equivalent of that is, for example, replacing a hydrogen atom with a **fluorine atom** (F) on the precursor chemical.

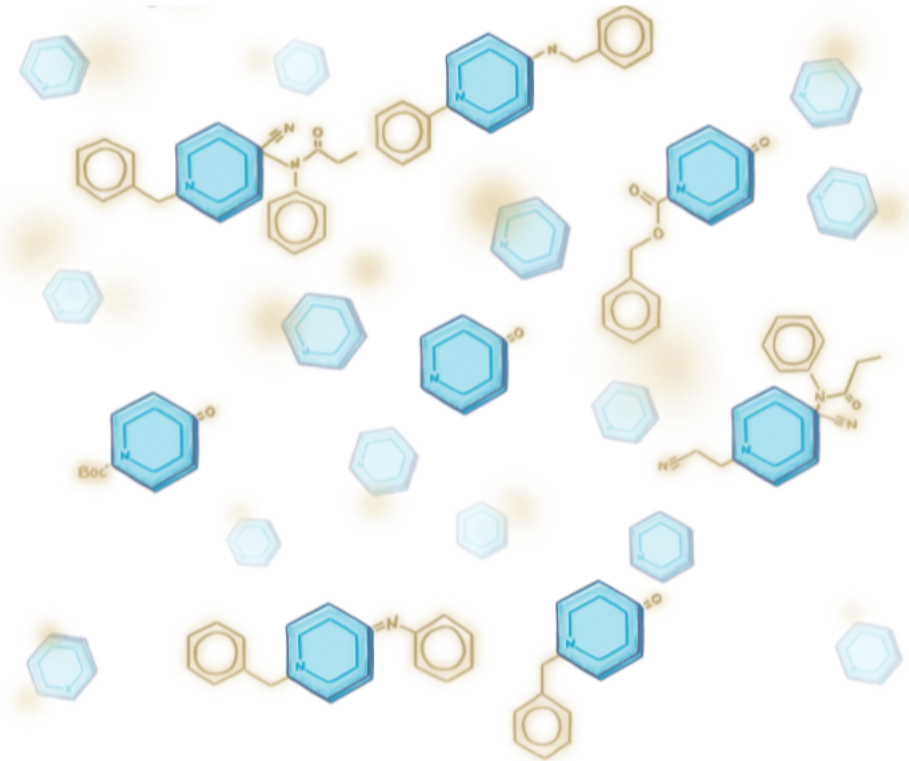


These changes help chemical sellers stay one step ahead of regulatory and interdiction efforts. The tweaked compounds can still be used to produce so-called **fentanyl analogs** that produce a similar high and are often just as dangerous — or even more dangerous — than fentanyl itself.

Here are three examples of fentanyl analogs common in the illicit drug market. **Carfentanil**, which was initially developed to sedate elephants and other large animals, is 100 times more potent than fentanyl, according to the DEA.

Comparison of potentially lethal doses



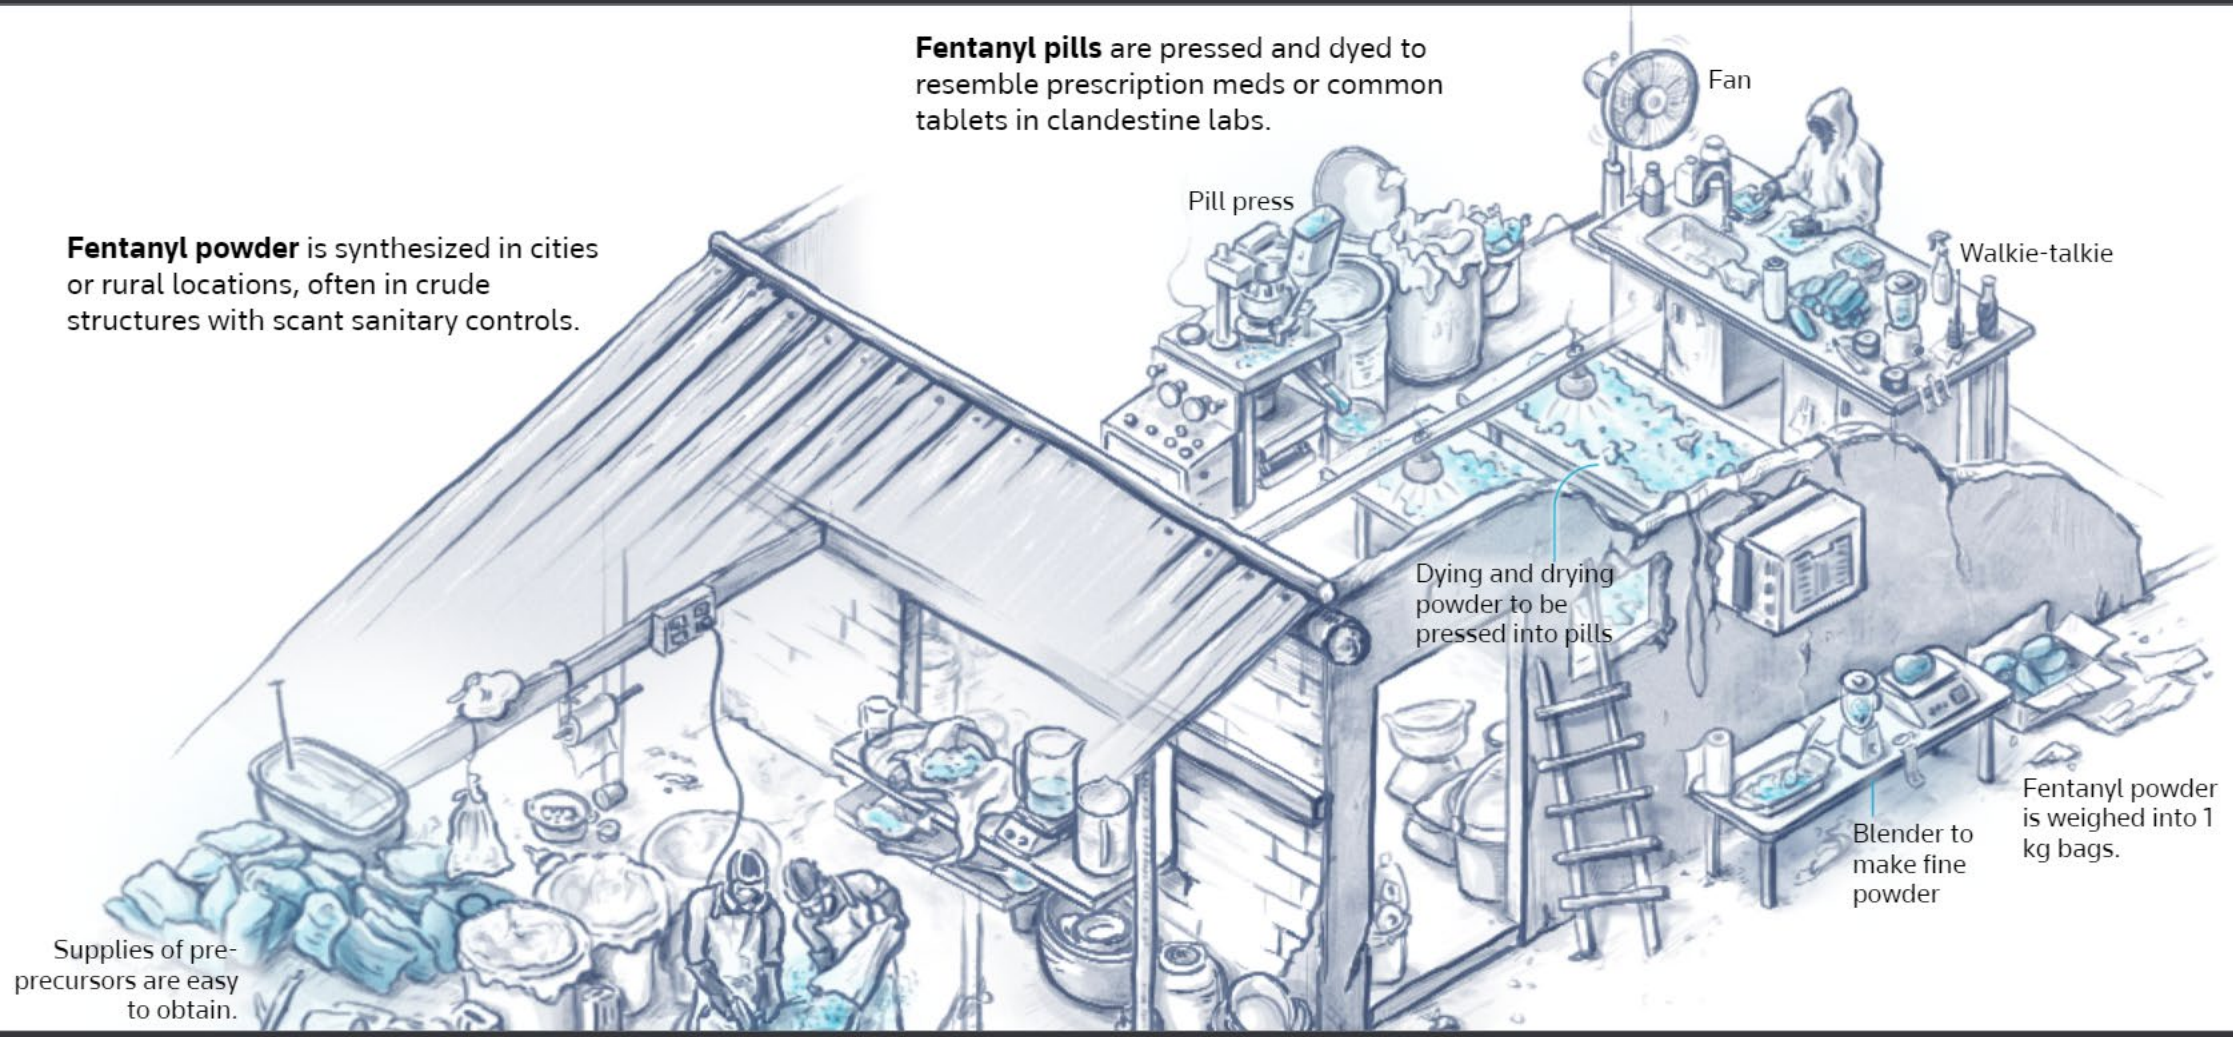


Pre-precursors

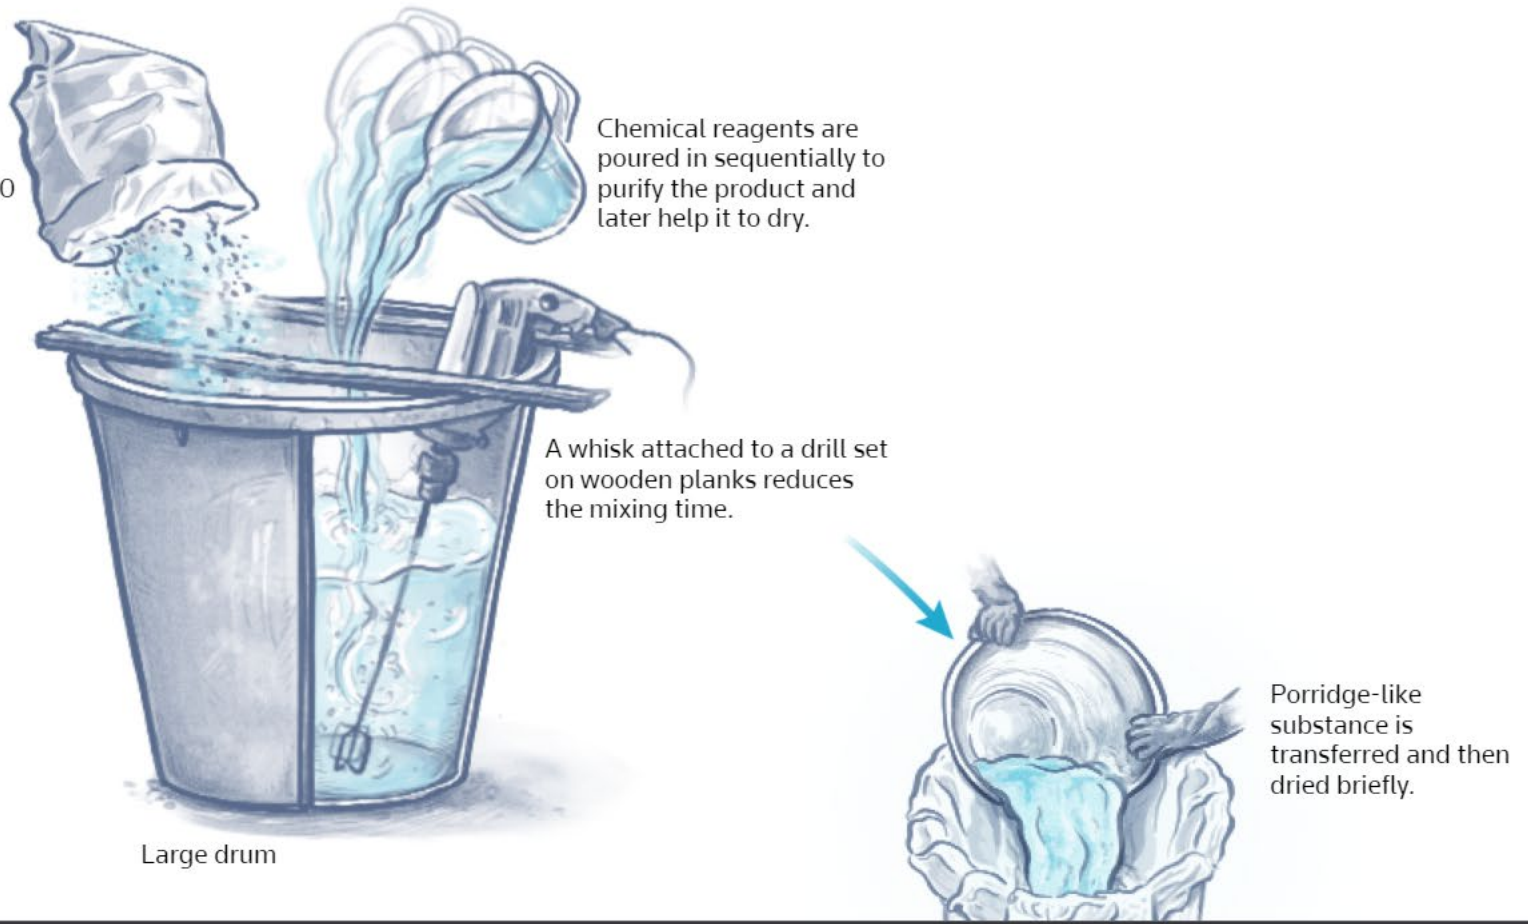
If packaged brownie mixes were banned, you could still make the dessert using eggs, chocolate, sugar and flour. That's the idea of **pre-precursors**.

These chemicals contain the all-important **piperidine ring**, and are the ingredients that can be used to create immediate precursors.

But legal industries also use pre-precursors to manufacture all sorts of goods, including fragrances, plastics, pesticides and lifesaving medications such as anti-tumor and anti-malarial drugs. That makes tightly regulating them much more complicated for authorities.



The process begins by adding "El 400" into the bucket.

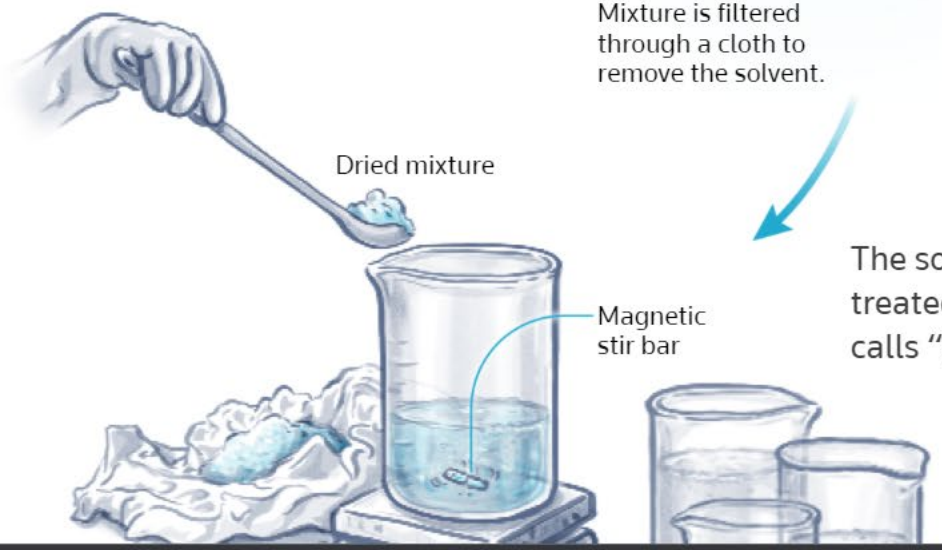


the mixing time.

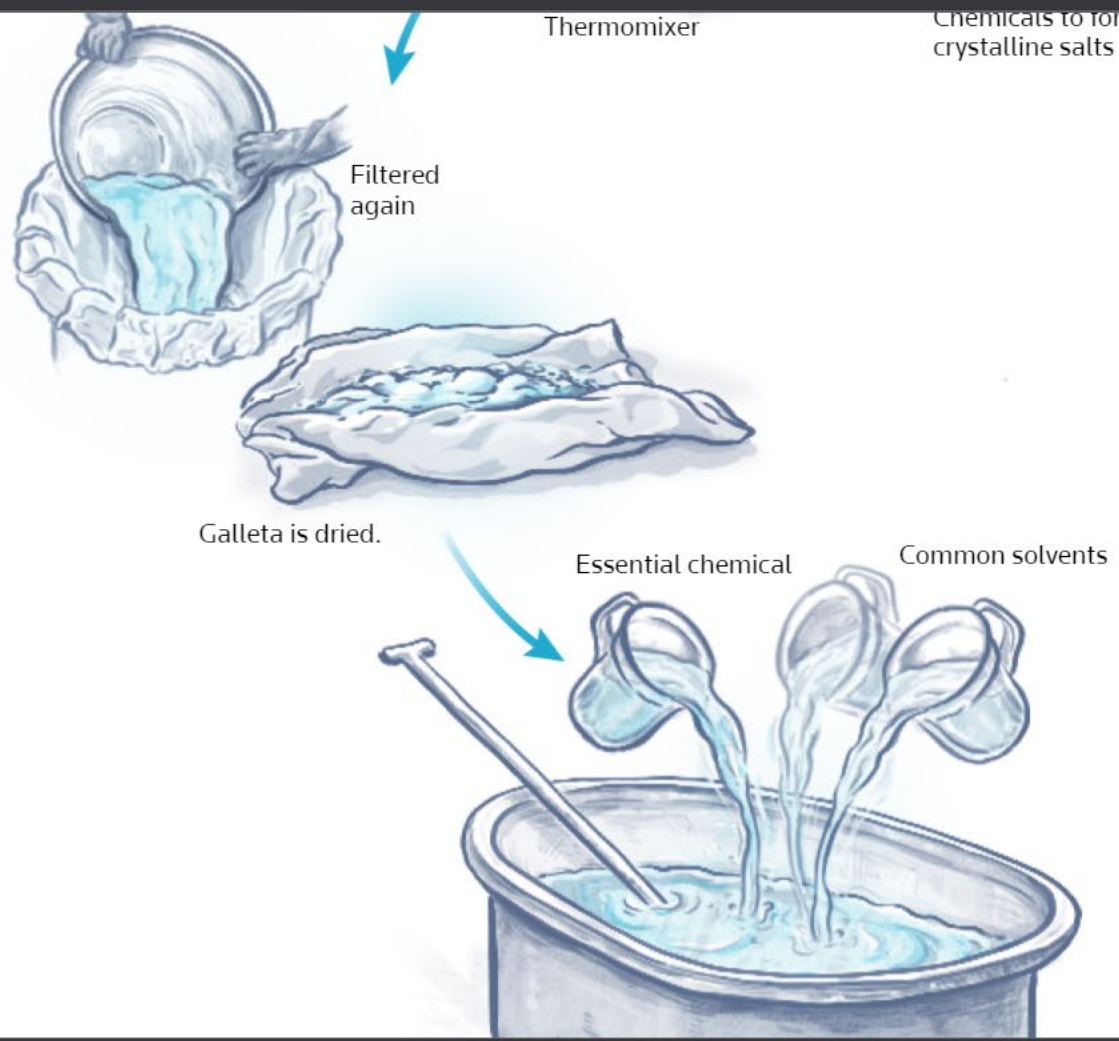
Large drum

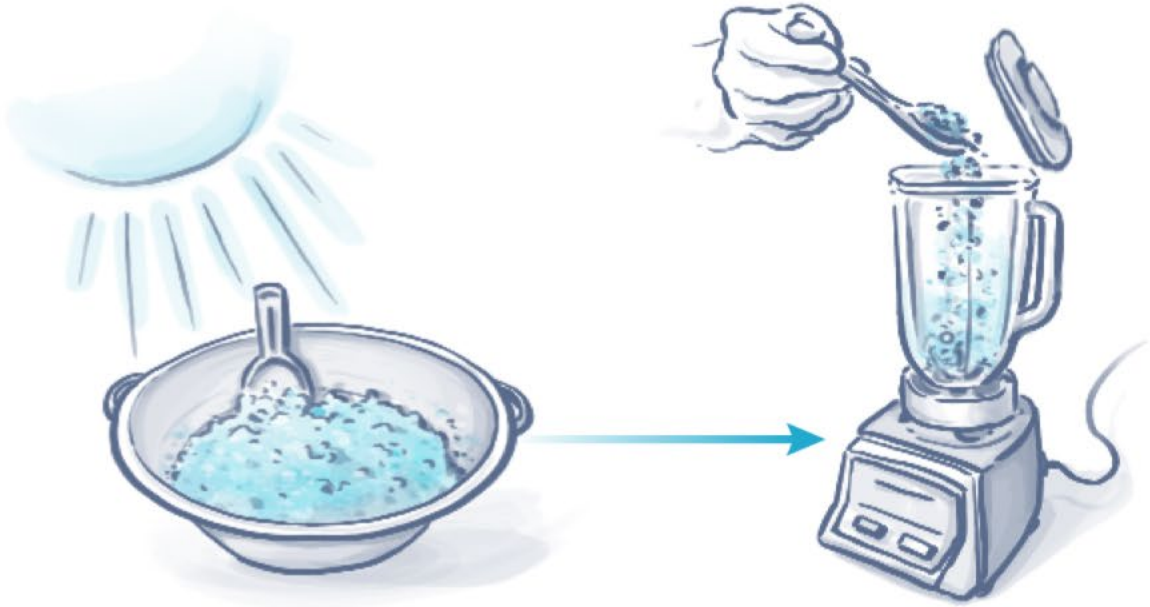
Porridge-like substance is transferred and then dried briefly.

Mixture is filtered through a cloth to remove the solvent.



The solution is mixed, cooled with ice and treated with a liquid to create what the cook calls "galleta," the Spanish word for cookie.



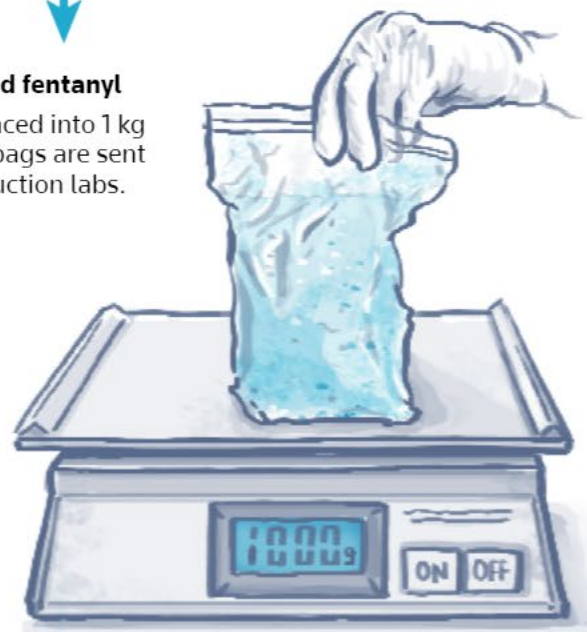


Fentanyl powder dries under the sun for a few hours.

The coarse powder is refined in a blender. This is a dangerous step: Cooks can overdose if they inhale the powder.

Powdered fentanyl

Powder is placed into 1 kg bags. Some bags are sent to post-production labs.

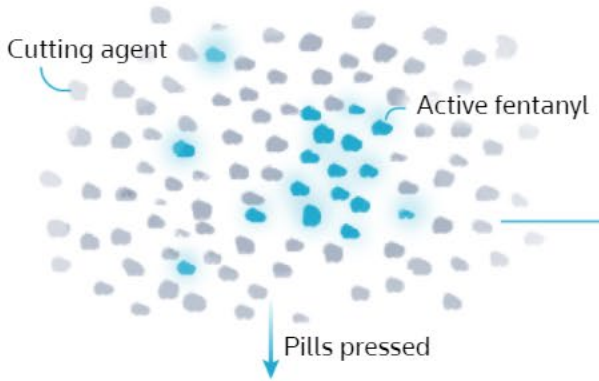


Pill-form fentanyl

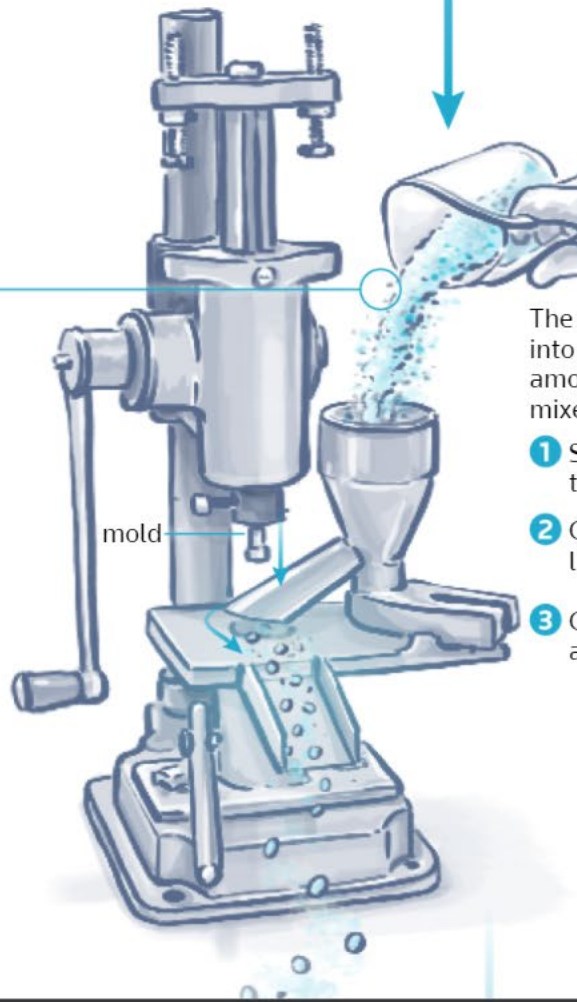
At those labs, pill die molds are used to press some of the powder into counterfeit pills that mimic oxycodone, a prescription painkiller.

Processing the fentanyl

and decrease its potency.



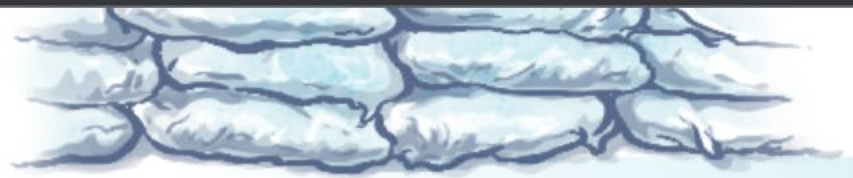
Like chocolate chips in a batch of cookies, the amount of active fentanyl in an illicit pill is never evenly distributed. The DEA has found tablets with widely varying amounts of active fentanyl – ranging from 0.01 mg to 8.4 mg per pill.



The powder to be pressed into pills includes tiny amounts of fentanyl mixed with:

1. Sugars to bulk up the product
2. Common painkillers like acetaminophen
3. Chemicals to bind and color the pills

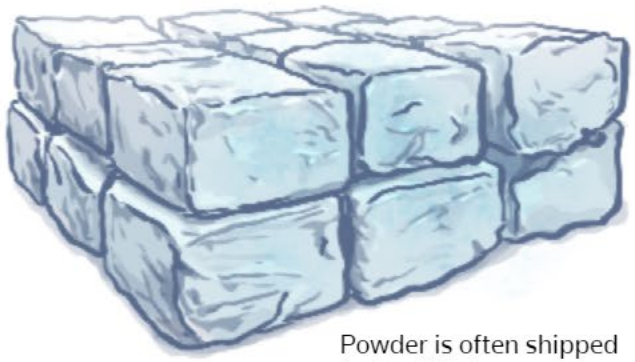
The most common sugar that Mexican producers add to fentanyl is mannitol, a low-calorie sweetener.



The powder is often cut again after crossing the border, especially with the powerful sedative xylazine, which can make fentanyl even more deadly.

Shipping the drug to the U.S.

The vast majority of fentanyl powder and pills entering the U.S. is smuggled across the border in vehicles driven by American citizens through legal ports of entry, according to U.S. authorities.



Powder is often shipped to the U.S. in pressed-brick form.

Some of the powder is transported to pill-press mills across the U.S. **A single kilo** of pure fentanyl can make around **500,000 pills**.

the signature markings of a generic version
of the prescription painkiller oxycodone.

PUBLIC ALERT

MAY 2024

MEDETOMIDINE RAPIDLY PROLIFERATING ACROSS USA — IMPLICATED IN RECREATIONAL OPIOID DRUG SUPPLY & CAUSING OVERDOSE OUTBREAKS

PURPOSE: The objective of this announcement is to notify public health, harm reduction, first responders, clinicians, medical examiners and coroners, forensic and clinical laboratories, and all other related communities about new information surrounding the emergent adulterant **medetomidine** (also referred to as dexmedetomidine).

BACKGROUND: Medetomidine is an alpha-2 agonist, belonging to the same family of drugs as xylazine and clonidine. Medetomidine is synthetically manufactured and exists in two enantiomeric forms: **dexmedetomidine** and levomedetomidine, the former being active and potent. Dexmedetomidine is approved for use in humans and is administered in hospital, while differing forms of medetomidine are available for use in veterinary medicine. The effects of **medetomidine** can include sedation, analgesia, muscle relaxation, anxiolysis, bradycardia, hypotension, hyperglycemia, and hallucinations. Duration of action is noted to be longer for medetomidine relative to xylazine.

SUMMARY: Medetomidine is the latest CNS depressant to appear as an adulterant alongside fentanyl in the recreational drug supply. Recent mass overdose outbreaks in Philadelphia, Chicago, and elsewhere have all been associated with fentanyl or heroin drug products containing medetomidine, as well xylazine and/or other substances. In cases where medetomidine ingestion is suspected or confirmed, severe adverse effects have been noted, including **heightened sedation and profound bradycardia**. In December 2023, the CFSRE and the Colombo Plan issued a ***Toxic Adulterant Alert*** for medetomidine following its emergence in the recreational drug supply.

TIMEFRAME	DESCRIPTION OF MEDETOMIDINE IDENTIFICATIONS AND OVERDOSE EVENTS
Late 2022	Medetomidine begins appearing more regularly in the **Maryland** drug supply, following its first detection in July 2022. Medetomidine is commonly identified alongside fentanyl, xylazine, and other substances.
Mid-to-Late 2023	Medetomidine is sporadically identified in toxicology specimens collected from patients presenting to emergency departments after suspected opioid overdose (confirmed to not be administered). Overdose events originated from **Missouri, Colorado, Pennsylvania, California, and Maryland**. Medetomidine is commonly detected with fentanyl.
January 2024	An **alert** is issued out of **Toronto, ON**, about the emergence of medetomidine in the drug supply. This is followed by increased positivity in subsequent weeks and months, as medetomidine is found alongside fentanyl in suspected opioid products and commonly in combination with xylazine and other substances.
Early 2024	Medetomidine detections increase in drug materials and toxicology specimens originating from western Canada, including **Vancouver, BC**, commonly alongside fentanyl and other opioids.
Late April 2024	Medetomidine first appears in drug products in **Philadelphia, PA**, causing a large scale outbreak of overdoses and adverse events. Medetomidine is identified alongside fentanyl and xylazine.
Early May 2024	Medetomidine first appears in a drug product in **Pittsburgh, PA**, associated with overdoses and adverse events. Medetomidine is identified alongside fentanyl and xylazine.
Early May 2024	Medetomidine first appears in drug products in **Chicago, IL**, causing a large scale outbreak of overdoses and adverse events. Medetomidine is identified alongside fentanyl and xylazine, or alongside heroin without xylazine.

• GEOGRAPHICAL DISTRIBUTION OF MEDETOMIDINE EMERGENCE

Medetomidine has been identified across several states in the U.S. and Canada, and is recently being observed in severe overdose outbreaks in major metropolitan areas.

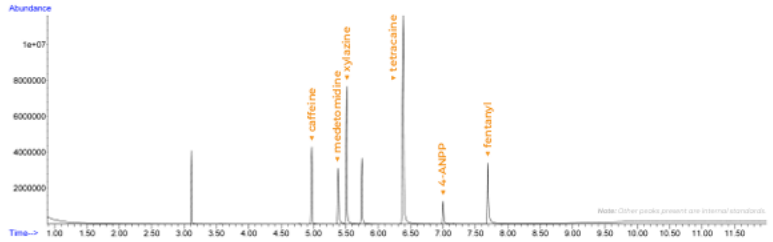
EXAMPLE CHROMATOGRAM OF A DRUG MATERIAL CONTAINING MEDETOMIDINE COLLECTED FROM PHILADELPHIA IN EARLY MAY 2024



DRUG MATERIALS CONTAINING MEDETOMIDINE AND OTHER SUBSTANCES

SUMMARY OF RESULTS:

- *To date, medetomidine has been commonly identified alongside fentanyl and xylazine, and the proportion of medetomidine in the drug material varies by sample.*
- *Medetomidine has been identified alongside heroin, in the absence of xylazine.*
- *Tetracaine has been identified alongside fentanyl, xylazine, and medetomidine in drug products, but not uniformly or consistently.*
- *Real-time drug material and toxicological testing are on-going to track the emergence and proliferation of medetomidine.*

ToxIC Fentalog Study Group — Quarterly NPS Report

CLINICAL **2024**

PURPOSE: This report provides new information regarding comprehensive drug testing of clinical toxicology specimens collected after suspected opioid overdoses in cities across the United States (U.S.).

OVERVIEW: Drug use can lead to adverse events and overdose scenarios where individuals present to emergency departments (EDs) for clinical evaluation and/or treatment. The culprit can be traditional drugs (e.g., heroin, fentanyl, cocaine, methamphetamine) or novel psychoactive substances (NPS); however, proper drug testing methodologies must be used for accurate identification and characterization. Street-level drug preparations can contain undeclared or unwanted substances (e.g., toxic adulterants or NPS) which can potentiate effects or lead to adverse reactions. Understanding emerging drug trends and drug testing results can help direct new or revised approaches to clinical treatment and harm reduction.

OBJECTIVE: A partnership between the American College of Medical Toxicology (ACMT) and the Center for Forensic Science Research and Education (CFSRE) was established to comprehensively assess the role and prevalence of synthetic opioids and other drugs among suspected overdose events in the U.S.

SAMPLE SOURCE: Patients presented to EDs within ACMT's Toxicology Investigators Consortium (ToxIC) experiencing a suspected opioid overdose. Residual, discarded biological samples were obtained for testing against an expansive library of drugs and other substances. Our findings provide a near real-time assessment of the drug market and allude to resulting implications on clinical institutions.

TOXICOLOGY TESTING: Analysis was performed via liquid chromatography quadrupole time-of-flight mass spectrometry (LC-QTOF-MS). The scope of testing targeted more than 1,200 drugs, including a vast majority of NPS and metabolites. Drug classes included opioids, benzodiazepines, cannabinoids,

PURPOSE: This report provides new information regarding comprehensive drug testing of toxicology specimens collected in clinical settings after suspected non-fatal opioid, stimulant, and other drug-related overdoses in cities across the United States (U.S.).

OVERVIEW: Drug use can lead to adverse events and overdose scenarios where individuals present to emergency departments (ED) for clinical evaluation and/or treatment. The culprit can be traditional drugs (e.g., heroin, fentanyl, cocaine, methamphetamine) or novel psychoactive substances (NPS); however, proper drug testing methodologies must be used for accurate identification and characterization. Street-level drug preparations may contain undeclared or unwanted substances (e.g., toxic adulterants, NPS) which can potentiate effects or lead to adverse reactions and unmasking scenarios. Understanding emerging drug trends and testing results can help direct new or revised approaches to clinical treatment and harm reduction.

OBJECTIVE: A partnership between the American College of Medical Toxicology (ACMT) and the Center for Forensic Science Research and Education (CFSRE) was established to comprehensively assess the role and prevalence of drugs, adulterants, NPS, and other relevant substances among suspected overdose events in the U.S.

SAMPLE SOURCE: Patients presented to EDs within the Toxicology Investigators Consortium (ToxIC) Drug Overdose Toxico-Surveillance (DOTS) Reporting Program experiencing a suspected opioid or simulant related overdose. Blood samples were obtained for testing against an expansive library of drugs and other substances. Our findings provide near real-time assessment of drug markets and allude to resulting implications on clinical and forensic institutions.

TOXICOLOGY TESTING: Analysis was performed via liquid chromatography quadrupole time-of-flight mass spectrometry (LC-QTOF-MS) and liquid chromatography tandem quadrupole mass spectrometry (LC-QQQ-MS). The scope of LC-QTOF-MS testing targeted more than 1,200 drugs, including a vast majority of NPS and metabolites. Drug classes included opioids, benzodiazepines, cannabinoids, stimulants, and hallucinogens, among other drugs. The LC-QQQ-MS test was quantitative, targeting fentanyl, norfentanyl, methamphetamine, amphetamine, cocaine, benzoylecgonine, xylazine, and naloxone. Additional targets included for quantitative testing were NPS of interest (e.g., bromazolam, cathinones, nitazene analogues, and others).
